DM545/DM871 Linear and Integer Programming

Lecture 7 Revised Simplex Method

Marco Chiarandini

Department of Mathematics & Computer Science University of Southern Denmark

Outline

1. Revised Simplex Method

2. Efficiency Issues

Motivation

Complexity of single pivot operation in standard simplex:

- entering variable O(n)
- leaving variable O(m)
- updating the tableau O(mn)

Problems with this:

- Time: we are doing operations that are not actually needed
 Space: we need to store the whole tableau: O(mn) floating point numbers
- Most problems have sparse matrices (many zeros) sparse matrices are typically handled efficiently the standard simplex has the 'Fill in' effect: sparse matrices are lost
- accumulation of Floating Point Errors over the iterations

Outline

1. Revised Simplex Method

2. Efficiency Issue:

Revised Simplex Method

Several ways to improve wrt pitfalls in the previous slide, requires matrix description of the simplex.

$$\max \sum_{j=1}^{n} c_j x_j$$

$$\sum_{j=1}^{n} a_{ij} x_j \le b_i \ i = 1..m$$

$$x_j \ge 0 \ j = 1..n$$

$$\begin{aligned} \max c^T x & \max\{c^T x \mid Ax = b, x \geq 0\} \\ & Ax = b \\ & x \geq 0 \\ & A \in \mathbb{R}^{m \times (n+m)} \\ & c \in \mathbb{R}^{(n+m)}, b \in \mathbb{R}^m, x \in \mathbb{R}^{n+m} \end{aligned}$$

At each iteration the simplex moves from a basic feasible solution to another.

For each basic feasible solution:

•
$$B = \{1 \dots m\}$$
 basis

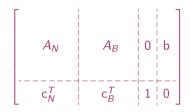

•
$$N = \{m+1...m+n\}$$

•
$$A_B = [a_1 \dots a_m]$$
 basis matrix

$$\bullet \ A_N = [\mathsf{a}_{m+1} \dots \mathsf{a}_{m+n}]$$

•
$$x_N = 0$$

•
$$x_B \ge 0$$

$$Ax = A_N x_N + A_B x_B = b$$
$$A_B x_B = b - A_N x_N$$

Basic feasible solution \iff A_B is non-singular

$$\mathsf{x}_B = A_B^{-1}\mathsf{b} - A_B^{-1}A_N\mathsf{x}_N$$

6

for the objective function:

$$z = c^T x = c_B^T x_B + c_N^T x_N$$

Substituting for x_B from above:

$$z = c_B^T (A_B^{-1} b - A_B^{-1} A_N \times_N) + c_N^T \times_N =$$

= $c_B^T A_B^{-1} b + (c_N^T - c_B^T A_B^{-1} A_N) \times_N$

Collecting together:

$$x_B = A_B^{-1}b - A_B^{-1}A_N x_N$$

$$z = c_B^T A_B^{-1}b + (c_N^T - c_B^T \underbrace{A_B^{-1}A_N}) x_N$$

In tableau form, for a basic feasible solution corresponding to B we have:

$$\begin{bmatrix} A_{B}^{-1}A_{N} & I & 0 & A_{B}^{-1}b \\ \hline c_{N}^{T} - c_{B}^{T}A_{B}^{-1}A_{N} & 0 & 1 & -c_{B}^{T}A_{B}^{-1}b \end{bmatrix}$$

We do not need to compute all elements of \bar{A}

Example

$$\begin{array}{ccc} \max & x_1 + x_2 \\ -x_1 + x_2 \leq 1 \\ x_1 & \leq 3 \\ & x_2 \leq 2 \\ & x_1, x_2 \geq 0 \end{array}$$

Initial tableau

$$\begin{vmatrix} x1 & x2 & x3 & x4 & x5 & -z & b \\ -1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 0 & 0 & 3 \\ -0 & 1 & 0 & 0 & 0 & 1 & 0 & 2 \\ -1 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ \end{vmatrix}$$

After two iterations

Basic variables x_1, x_2, x_4 . Non basic: x_3, x_5 . From the initial tableau:

$$A_{B} = \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \quad A_{N} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix} \quad x_{B} = \begin{bmatrix} x_{1} \\ x_{2} \\ x_{4} \end{bmatrix} \quad x_{N} = \begin{bmatrix} x_{3} \\ x_{5} \end{bmatrix}$$

$$c_B^T = \begin{bmatrix} 1 \ 1 \ 0 \end{bmatrix} \quad c_N^T = \begin{bmatrix} 0 \ 0 \end{bmatrix}$$

• Entering variable:

in std. we look at tableau, in revised we need to compute: $c_N^T - c_B^T A_R^{-1} A_N$

- 1. find $y^T = c_B^T A_B^{-1}$ (by solving $y^T A_B = c_B^T$, the latter can be done more efficiently)
- 2. calculate $c_N^T y^T A_N$

•

Step 1:

$$\begin{bmatrix} y_1 & y_2 & y_3 \end{bmatrix} \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} -1 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & -1 \end{bmatrix} = \begin{bmatrix} -1 & 0 & 2 \end{bmatrix}$$

Step 2:

$$\begin{bmatrix} 0 & 0 \end{bmatrix} - \begin{bmatrix} -1 & 0 & 2 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & -2 \end{bmatrix}$$

(Note that they can be computed individually: $c_j - y^T a_j > 0$) Let's take the first we encounter x_3

$$y^T A_B = c_B^T$$

$$c_B^T A_B^{-1} = y^T$$

$$c_N^T - y^T A_N$$

• Leaving variable

we increase variable by largest feasible amount $\boldsymbol{\theta}$

R1:
$$x_1 - x_3 + x_5 = 1$$

R2: $x_2 + 0x_3 + x_5 = 2$

R3:
$$-x_3 + x_4 - x_5 = 2$$

$$x_B = x_B^* - A_B^{-1} A_N x_N$$
$$x_B = x_B^* - d\theta$$

$$x_1 = 1 + x_3 \ge 0$$
$$x_2 = 2 \ge 0$$

 $x_4 = 2 - x_3 > 0$

d is the column of $A_B^{-1}A_N$ that corresponds to the entering variable, ie, $d = A_B^{-1}a$ where a is the entering column

3. Find θ such that x_B stays positive: Find $d = A_B^{-1}a$ (by solving $A_Bd = a$)

Step 3:

$$\begin{bmatrix} d_1 \\ d_2 \\ d_3 \end{bmatrix} = \begin{bmatrix} -1 & 0 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \implies \mathsf{d} = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \implies \mathsf{x}_B = \begin{bmatrix} 1 \\ 2 \\ 2 \end{bmatrix} - \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} \theta \ge 0$$

$$2-\theta \ge 0 \implies \theta \le 2 \rightsquigarrow x_4$$
 leaves

• So far we have done computations, but now we save the pivoting update. The update of A_B is done by replacing the leaving column by the entering column

$$x_{B}^{*} = \begin{bmatrix} x_{1} - d_{1}\theta \\ x_{2} - d_{2}\theta \\ \theta \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \\ 2 \end{bmatrix} \qquad A_{B} = \begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$$

- Many implementations depending on how $y^T A_B = c_B^T$ and $A_B d = a$ are solved. They are in fact solved from scratch.
- many operations saved especially if many variables!
- special ways to call the matrix A from memory
- better control over numerical issues since A_B^{-1} can be recomputed.

Revised Simplex Method Efficiency Issues

Outline

1. Revised Simplex Method

2. Efficiency Issues

Solving the two Systems of Equations

 $A_{BX} = b$ solved without computing A_{B}^{-1} (costly and likely to introduce numerical inaccuracy)

Recall how the inverse is computed:

For a 2×2 matrix

the matrix inverse is

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} d & -c \\ -b & a \end{bmatrix}^{T} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

For a 3×3 matrix

the matrix inverse is

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} +\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + \begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} \end{bmatrix}^{T}$$

$$A^{-1} = \frac{1}{|A|} \begin{bmatrix} -\begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} + \begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix} - \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix} + \begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - \begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \end{bmatrix}$$

Eta Factorization of the Basis

Let $B := A_B$, kth iteration B_k be the matrix with col p differing from B_{k-1} Column p is the a column appearing in $B_{k-1}d = a$ solved at 3) Hence:

$$B_k = B_{k-1}E_k$$

 E_k is the eta matrix differing from id. matrix in only one column, which is set equal to d

$$\begin{bmatrix} -1 & 1 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} = \begin{bmatrix} -1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 0 \\ & 1 \end{bmatrix}$$

No matter how we solve $y^T B_{k-1} = c_B^T$ and $B_{k-1} d = a$, their update always relays on $B_k = B_{k-1} E_k$ with E_k available. Plus when initial basis by slack variable $B_0 = I$ and $B_1 = E_1, B_2 = E_1 E_2 \cdots$:

$$B_k = E_1 E_2 \dots E_k$$
 eta factorization

$$(((((y^{T}E_{1})E_{2})E_{3})\cdots)E_{k} = c_{B}^{T}, \qquad u^{T}E_{4} = c_{B}^{T}, \ v^{T}E_{3} = u^{T}, \ w^{T}E_{2} = v^{T}, \ y^{T}E_{1} = w^{T}$$
$$(E_{1}(E_{2}\cdots E_{k}d)) = a, \qquad E_{1}u = a, \ E_{2}v = u, \ E_{3}w = v, \ E_{4}d = w$$

Exercise

Solve the systems $y^T E_1 E_2 E_3 E_4 = [1\ 2\ 3]$ and $E_1 E_2 E_3 E_4 d = [1\ 2\ 3]^T$ with

$$E_1 = \begin{bmatrix} 1 & 3 & 0 \\ 0 & 0.5 & 0 \\ 0 & 4 & 1 \end{bmatrix} \qquad E_2 = \begin{bmatrix} 2 & 0 & 0 \\ 1 & 1 & 0 \\ 4 & 0 & 1 \end{bmatrix} \qquad E_3 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 1 \end{bmatrix} \qquad E_4 = \begin{bmatrix} -0.5 & 0 & 0 \\ 3 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

We use backward transformation and solve the sequence of linear systems:

$$u^{T}E_{4} = [1 \ 2 \ 3], \quad v^{T}E_{3} = u^{T}, \quad w^{T}E_{2} = v^{T}, \quad y^{T}E_{1} = w^{T}$$

$$\mathbf{u}^T \begin{bmatrix} -0.5 & 0 & 0 \\ 3 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = [1, 2, 3]$$

Since the eta matrices have always one 1 in two columns then the solution can be read up easily. From the third column we find $u_3 = 3$. From the second column, we find $u_2 = 2$. Substituting in the first column, we find $-0.5u_1 + 3 * 2 + 1 * 3 = 1$, which yields $u_1 = 16$. The next syestem is:

$$v^T \begin{vmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 1 \end{vmatrix} = [16, 2, 3]$$

From the first column we get $v_1 = 16$, from the second column $v_2 = 2$ from the last column $v_1 + 3v_2 + v_3 = 3$, which yields $v_3 = -19$. The next:

$$\mathbf{w}^{T} \begin{bmatrix} 2 & 0 & 0 \\ 1 & 1 & 0 \\ 4 & 0 & 1 \end{bmatrix} = [16, 2, -19]$$

- Solving $y^T B_k = c_B^T$ also called backward transformation (BTRAN)
- Solving $B_k d = a$ also called forward transformation (FTRAN)
- E_i matrices can be stored by only storing the column and the position
- If sparse columns then can be stored in compact mode, ie only nonzero values and their indices

More on LP

- Tableau method is unstable: computational errors may accumulate. Revised method has a natural control mechanism: we can recompute A_B^{-1} at any time
- Commercial and freeware solvers differ from the way the systems $y^T A_B = c_B^T$ and $A_B d = a$ are resolved

Efficient Implementations

- Dual simplex with steepest descent (largest increase)
- Linear Algebra:
 - Dynamic LU-factorization using Markowitz threshold pivoting (Suhl and Suhl, 1990)
 - sparse linear systems: Typically these systems take as input a vector with a very small number of nonzero entries and output a vector with only a few additional nonzeros.
- Presolve, ie problem reductions: removal of redundant constraints, fixed variables, and other extraneous model elements.
- dealing with degeneracy, stalling (long sequences of degenerate pivots), and cycling:
 - bound-shifting (Paula Harris, 1974)
 - Hybrid Pricing (variable selection): start with partial pricing, then switch to devex (approximate steepest-edge, Harris, 1974)
- A model that might have taken a year to solve 10 years ago can now solve in less than 30 seconds (Bixby, 2002).

Further topics in LP

- Ellipsoid method: cannot compete in practice but polynomial time (Khachyian, 1979)
- Interior point algorithm(s) (Karmarkar, 1984) competitive with simplex and polynomial in some versions
 - iterate through points interior to the feasibility region
 - because of patents reasons, also known as barrier algorithm
 - one single iteration is computationally more intensive than the simplex
 - particularly competitive in presence of many constraints (eg, for m = 10,000 may need less than 100 iterations)
 - bad for post-optimality analysis \leadsto crossover algorithm to convert a sol of barrier method into a basic feasible solutions for the simplex
- Lagrangian relaxation
- Column generation
- Decomposition methods:
 - Dantzig Wolfe decomposition
 - Benders decomposition

Interior Point Algorithm

- 1. Start at an interior point of the feasible region
- 2. Move in a direction that improves the objective function value at the fastest possible rate
- 3. Transform the feasible region to place the current point at the center of it

How Large Problems Can We Solve?

Very large model				
	Rows	Columns	Nonzeros	
Original size	5034171	7365337	25596099	
After presolve	1296075	2910559	10339042	

Solution times were as follows:

Very large model—solution times				
	Algorithm			
Version	Barrier	Dual	Primal	
CPLEX 5.0	8642.6	350000.0	71039.7	
CPLEX 7.1	5642.6	6413.1	1880.0	

Suppose you were given the following choices:

- Option 1: Solve a MIP with today's solution technology on a machine from 1991
- Option 2: Solve a MIP with 1991 solution technology on a machine from today

Which option should you choose?
