Outline

Outline

A Numerical Example

$$\max \ \sum_{j=1}^{n} c_j x_j$$
$$\sum_{j=1}^{n} a_{ij} x_j \ \leq b_i, \ \ i = 1, \ldots, m$$
$$x_j \ \geq 0, \ \ j = 1, \ldots, n$$

$$\max \ 6x_1 \ + \ 8x_2$$
$$5x_1 \ + \ 10x_2 \ \leq \ 60$$
$$4x_1 \ + \ 4x_2 \ \leq \ 40$$
$$x_1, x_2 \ \geq \ 0$$

$$\max \ c^T x$$
$$Ax \ \leq \ b$$
$$x \ \geq \ 0$$

$$x \in \mathbb{R}^n, c \in \mathbb{R}^n, A \in \mathbb{R}^{m \times n}, b \in \mathbb{R}^m$$

$$\max \ \begin{bmatrix} 6 & 8 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

$$\begin{bmatrix} 5 & 10 \\ 4 & 4 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 60 \\ 40 \end{bmatrix}$$

$$x_1, x_2 \ \geq \ 0$$

Outline

Standard Form

Every LP problem can be converted in the standard form:

$$\max \ c^T x$$
$$A x \ \leq \ b$$
$$x \ \in \ \mathbb{R}^n$$

$$c \in \mathbb{R}^n, A \in \mathbb{R}^{m \times n}, b \in \mathbb{R}^m$$

- if equations, then put two constraints, $ax \leq b$ and $ax \geq b$
- if $ax \geq b$ then $-ax \leq -b$
- if $\min c^T x$ then $-\max(-c^T x)$

and then be put in equational standard form:

$$\max \ c^T x$$
$$A x \ = \ b$$
$$x \ \geq \ 0$$

$$x \in \mathbb{R}^n, c \in \mathbb{R}^n, A \in \mathbb{R}^{m \times n}, b \in \mathbb{R}^m$$

1. "=" constraints
2. $x \geq 0$ nonnegativity constraints
3. ($b \geq 0$)
4. max

Transformation to Std Form

Every LP problem can be transformed in eq. std. form

1. introduce slack variables (or surplus)

$$5x_1 + 10x_2 + x_3 = 60$$
$$4x_1 + 4x_2 + x_4 = 40$$

2. if $x_1 \gtreqless 0$ then
$$x_1 = x_1' - x_1''$$
$$x_1' \geq 0$$
$$x_1'' \geq 0$$

3. $(b \geq 0)$

4. $\min c^T x \equiv -\max(-c^T x)$

LP in $m \times n$ converted into LP with at most $(m + 2n)$ variables and m equations (n # original variables, m # constraints)
Geometry of LP in Eq. Std. Form

$$\max\{c^T x \mid A x = b, x \geq 0\}$$

From linear algebra:

- the set of solutions of $Ax = b$ is an affine space (hyperplane not passing through the origin).
- $x \geq 0$ nonegative orthant (octant in $\mathbb{R}^3$)

In $\mathbb{R}^3$:

x_3

The set of all solutions of $A\mathbf{x} = \mathbf{b}$ (a plane)

The set of all feasible solutions (a triangle)

x_1

$\mathbf{0}$

x_2

- $A\mathbf{x} = \mathbf{b}$ is a system of equations that we can solve by Gaussian elimination

- Elementary row operations of $[A \mid \mathbf{b}]$ do not affect set of feasible solutions
  - multiplying all entries in some row of $[A \mid \mathbf{b}]$ by a nonzero real number λ
  - replacing the ith row of $[A \mid \mathbf{b}]$ by the sum of the ith row and jth row for some $i \neq j$

- Let n' be the number of vars in eq. std. form.

  $$\text{we assume } n' \geq m \text{ and } \mathrm{rank}([A \mid \mathbf{b}]) = \mathrm{rank}(A) = m$$

  ie, rows of A are linearly independent
  otherwise, remove linear dependent rows

Outline

Basic Feasible Solutions

Basic feasible solutions are the vertices of the feasible region:
More formally:

Let $B = \{1 \dots m\}$, $N = \{m + 1 \dots n + m = n'\}$ be subsets partitioning the columns of A: A_B be made of columns of A indexed by B:

Definition

$x \in \mathbb{R}^n$ is a basic feasible solution of the linear program $\max\{c^T x \mid Ax = b, x \geq 0\}$ for an index set B if:

- $x_j = 0 \ \forall j \notin B$
- the square matrix A_B is nonsingular, ie, all columns indexed by B are lin. indep.
- $x_B = A_B^{-1} b$ is nonnegative, ie, $x_B \geq 0$ (feasibility)

We call x_j for $j \in B$ basic variables and remaining variables nonbasic variables.

Theorem

A basic feasible solution is uniquely determined by the set B.

Proof:

$$A\mathsf{x} = A_B\mathsf{x}_B + A_N\mathsf{x}_N = b$$
$$\mathsf{x}_B + A_B^{-1}A_N\mathsf{x}_N = A_B^{-1}b$$
$$\mathsf{x}_B = A_B^{-1}b \qquad\qquad A_B \text{ is nonsingular hence one solution}$$

Note: we call B a (feasible) basis

Definition

A basic feasible solution of a linear program with n variables is a feasible solution for which some n linearly independent constraints hold with equality.

Extreme points and basic feasible solutions are geometric and algebraic manifestations of the same concept:

Theorem

Let P be a (convex) polyhedron from LP in eq. std. form. For a point $v \in P$ the following are equivalent:

(i) v is an extreme point (vertex) of P

(ii) v is a basic feasible solution of LP

Proof: see text book [MG] sec. 4.4.

Theorem

Let $LP = \max\{c^T x \mid Ax = b, x \geq 0\}$ be feasible and bounded,
then an optimal solution is a basic feasible solution.

Proof. consequence of previous theorem and fundamental theorem of linear programming

A similar theorem is valid for arbitrary linear programs (not in eq. form)

However, an optimal solution does not need to be basic:

$\max x_1 + x_2$ subject to $x_1 + x_2 \leq 1$

- Idea for solution method:

- examine all basic solutions.

- There are finitely many: $\binom{m+n}{m}$.

- However, if $n = m$ then $\binom{2m}{m} \approx 4^m$.

Outline

Simplex Method

$$\max \quad z = \begin{bmatrix} 6 & 8 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

Canonical eq. std. form: one decision variable is isolated in each constraint with coefficient 1 and does not appear in the other constraints nor in the obj. func. and b terms are positive

$$\begin{bmatrix} 5 & 10 & 1 & 0 \\ 4 & 4 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} = \begin{bmatrix} 60 \\ 40 \end{bmatrix}$$

$$x_1, x_2, x_3, x_4 \geq 0$$

It gives immediately a basic feasible solution:

$$x_1 = 0, \ x_2 = 0, \ x_3 = 60, \ x_4 = 40$$

Is it optimal? Look at signs in $z \rightsquigarrow$ if positive then an increase would improve.

Let's try to increase a promising variable, ie, x_1, one with positive coefficient in z

$$5x_1 + x_3 = 60$$
$$x_1 = \frac{60}{5} - \frac{x_3}{5}$$
$$x_3 = 60 - 5x_1 \geq 0$$

If $x_1 > 12$ then $x_3 < 0$

$5x_1 + x_3 = 60$

$$4x_1 + x_4 = 40$$
$$x_1 = \frac{40}{4} - \frac{x_4}{4}$$
$$x_4 = 40 - 4x_1 \geq 0$$

If $x_1 > 10$ then $x_4 < 0$

$4x_1 + x_4 = 40$

we can take the minimum of the two $\rightsquigarrow x_1$ increased to 10
x_1 enters the basis and x_4 leaves it.

Dictionary Form

Hence, we increase x_1 to 10 and consequently set $x_4 = 0$
That is, x_1 enters the basis and x_4 leaves it.

$$\max \; 6x_1 + 8x_2$$
$$5x_1 + 10x_2 + x_3 \qquad = 60$$
$$4x_1 + 4x_2 \qquad + x_4 = 40$$
$$x_1, x_2 \geq 0$$

$$x_3 = 60 - 5x_1 - 10x_2$$
$$\underline{x_4 = 40 - 4x_1 - 4x_2}$$
$$z = \qquad + 6x_1 + 8x_2$$

$$x_3 = 10 - 5x_2 + 5/4x_2$$
$$\underline{x_1 = 10 - x_2 - 1/4x_4}$$
$$z = 60 + 2x_2 - 6/4x_4$$

Simplex Tableau

First simplex tableau:

	x_1	x_2	x_3	x_4	$-z$	b
x_3	5	10	1	0	0	60
x_4	4	4	0	1	0	40
	6	8	0	0	1	0

we want to reach this new tableau

	x_1	x_2	x_3	x_4	$-z$	b
x_3	0	?	1	?	0	?
x_1	1	?	0	?	0	?
	0	?	0	?	1	?

Pivot operation:

1. Choose pivot:

   column: one s with positive coefficient in obj. func.

   row: ratio between coefficient b and pivot column: choose the one with smallest ratio:

   $$\theta = \min_i \left\{ \frac{b_i}{a_{is}} : a_{is} > 0 \right\}, \qquad \theta \text{ increase value of entering var.}$$

2. elementary row operations to update the tableau

- x_4 leaves the basis, x_1 enters the basis
  - Divide pivot row by pivot
  - Send to zero the coefficient in the pivot column of the first row
  - Send to zero the coefficient of the pivot column in the third (cost) row

```
|                 | x1 | x2 | x3 | x4   | -z |   b  |
|-----------------+----+----+----+------+----+------|
| I'=I-5II'       | 0  | 5  | 1  | -5/4 | 0  |  10  |
| II'=II/4        | 1  | 1  | 0  | 1/4  | 0  |  10  |
|-----------------+----+----+----+------+----+------|
| III'=III-6II'   | 0  | 2  | 0  | -6/4 | 1  | -60  |
```

From the last row we read: $2x_2 - 3/2x_4 - z = -60$, that is: $z = 60 + 2x_2 - 3/2x_4$.
Since x_2 and x_4 are nonbasic we have $z = 60$ and $x_1 = 10, x_2 = 0, x_3 = 10, x_4 = 0$.

- Done? No! Let x_2 enter the basis

```
|                 | x1 | x2 | x3   | x4   | -z |   b  |
|-----------------+----+----+------+------+----+------|
| I'=I/5          | 0  | 1  | 1/5  | -1/4 | 0  |  2   |
| II'=II-I'       | 1  | 0  | -1/5 | 1/2  | 0  |  8   |
|-----------------+----+----+------+------+----+------|
| III'=III-2I'    | 0  | 0  | -2/5 | -1   | 1  | -64  |
```

Definition (Reduced costs)

We call reduced costs the coefficients in the objective function of the nonbasic variables, $\bar{c}_N$

Proposition (Optimality Condition)

The basic feasible solution is optimal when the reduced costs in the corresponding simplex tableau are nonpositive, ie, such that:
$$\bar{c}_N \leq 0$$

Proof: Let z_0 be the obj value when $\bar{c}_N \leq 0$.
For any other feasible solution $\tilde{x}$ we have:

$$\tilde{x}_N \geq 0 \quad \text{and} \quad c^T \tilde{x} = z_0 + \bar{c}_N^T \tilde{x}_N \leq z_0$$

Graphical Representation

Outline

Tableaux and Dictionaries

$$\max \; \sum_{j=1}^{n} c_j x_j$$
$$\sum_{j=1}^{n} a_{ij} x_j \leq b_i, \; i = 1, \ldots, m$$
$$x_j \geq 0, \; j = 1, \ldots, n$$

$$x_{n+i} = b_i - \sum_{j=1}^{n} a_{ij} x_j, \quad i = 1, \ldots, m$$
$$z = \sum_{j=1}^{n} c_j x_j$$

Tableau

$$\begin{bmatrix} I & \bar{A}_N & 0 & \bar{b} \\ \hline 0 & \bar{c}_N & 1 & -\bar{d} \end{bmatrix}$$

Dictionary

$$x_r = \bar{b}_r - \sum_{s \notin B} \bar{a}_{rs} x_s, \quad r \in B$$
$$z = \bar{d} + \sum_{s \notin B} \bar{c}_s x_s$$

pivot operations in dictionary form:
choose col s with r.c. > 0
choose row with $\min\{-\bar{b}_i / \bar{a}_{is} \mid a_{is} < 0, i = 1, \ldots, m\}$
update: express entering variable and substitute in other rows

Example

$$\begin{aligned}
\max \ & 6x_1 + 8x_2 \\
& 5x_1 + 10x_2 \le 60 \\
& 4x_1 + 4x_2 \le 40 \\
& x_1, x_2 \ge 0
\end{aligned}$$

	x_1	x_2	x_3	x_4	$-z$	b
x_3	5	10	1	0	0	60
x_4	4	4	0	1	0	40
	6	8	0	0	1	0

$$\begin{aligned}
x_3 &= 60 - 5x_1 - 10x_2 \\
x_4 &= 40 - 4x_1 - 4x_2 \\
\hline
z &= + 6x_1 + 8x_2
\end{aligned}$$

After 2 iterations:

	x_1	x_2	x_3	x_4	$-z$	b
x_2	0	1	1/5	$-1/4$	0	2
x_1	1	0	$-1/5$	1/2	0	8
	0	0	$-2/5$	-1	1	-64

$$\begin{aligned}
x_2 &= 2 - 1/5 x_3 + 1/4 x_4 \\
x_1 &= 8 + 1/5 x_3 - 1/2 x_4 \\
\hline
z &= 64 - 2/5 x_3 - 1 x_4
\end{aligned}$$

Summary
